# Read

---

- ❖ File type: .txt, .csv
- ❖ Functions: read.table, read.csv

```
read.table(file, header = FALSE, sep = "", quote = "\"'",  
          dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),  
          row.names, col.names, as.is = !stringsAsFactors,  
          na.strings = "NA", colClasses = NA, nrows = -1,  
          skip = 0, check.names = TRUE, fill = !blank.lines.skip,  
          strip.white = FALSE, blank.lines.skip = TRUE,  
          comment.char = "#",  
          allowEscapes = FALSE, flush = FALSE,  
          stringsAsFactors = default.stringsAsFactors(),  
          fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)  
  
read.csv(file, header = TRUE, sep = ",", quote = "\"",  
         dec = ".", fill = TRUE, comment.char = "", ...)
```

---

# Write

---

- ❖ txt, csv
- ❖ x: (output data, notice the format)
- ❖ file: file name of the output data (notice the directory)
- ❖ row.names: whether keep names of rows
- ❖ col.names: whether keep names of columns

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",  
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,  
            col.names = TRUE, qmethod = c("escape", "double"),  
            fileEncoding = "")
```

```
write.csv(...)  
write.csv2(...)
```

# How to Define Function

Name

Return value of the input values.

Usage

```
max(..., na.rm = FALSE)
min(..., na.rm = FALSE)
```

```
pmax(..., na.rm = FALSE)
pmin(..., na.rm = FALSE)
```

```
pmax.int(..., na.rm = FALSE)
pmin.int(..., na.rm = FALSE)
```

Input

Arguments

... numeric or character arguments (see Note).

na.rm a logical indicating whether missing values should be removed.

Details

max and min return the maximum or minimum of *all* the values present in their arguments, as [integer](#) if all are logical or integer, as [double](#) if all are numeric, and character otherwise.

If na.rm is FALSE an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

The minimum and maximum of a numeric empty set are +Inf and -Inf (in this order!) which ensures *transitivity*, e.g., `min(x1, min(x2)) == min(x1, x2)`. For numeric `x` `max(x) == -Inf` and `min(x) == +Inf` whenever `length(x) == 0` (after removing missing values if requested). However, `pmax` and `pmin` return NA if all the parallel elements are NA even for `na.rm = TRUE`.

`pmax` and `pmin` take one or more vectors (or matrices) as arguments and return a single vector giving the 'parallel' maxima (or minima) of the vectors. The first element of the result is the maximum (minimum) of the first elements of all the arguments, the second element of the result is the maximum (minimum) of the second elements of all the arguments and so on. Shorter inputs (of non-zero length) are recycled if necessary. Attributes (see [attributes](#): such as [names](#) or [dim](#)) are copied from the first argument (if applicable).

`pmax.int` and `pmin.int` are faster internal versions only used when all arguments are atomic vectors and there are no classes: they drop all attributes. (Note that all versions fail for raw and complex vectors since these have no ordering.)

`max` and `min` are generic functions: methods can be defined for them individually or via the [Summary](#) group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

By definition the maximum (minimum) of a vector containing an NaN is NaN, except that the min/max of any vector containing an NA is NA even if it also contains an NaN. Note that `max(NA, Inf) == NA` even though the maximum would be Inf what if there were no other values?

Character vectors are ordered lexicographically, and this depends on the collating sequence of the locale in use: the help for '[Comparison](#)' gives details. The max/min of an empty character vector is defined to be character NA. (One could argue that as a special case, the maximum should be "", but there is no obvious candidate for the minimum.)

Output

Value

For min or max, a length-one vector. For pmin or pmax, a vector of length the longest of the input vectors, or length zero if one of the inputs had zero length.

The type of the result will be that of the highest of the inputs in the hierarchy integer < double < character.

For min and max if there are only numeric inputs and all are empty (after possible removal of NAs), the result is double (Inf or -Inf).

---

# How to Define Function

---

```
Function_Name = function(arg1, arg2...)
```

```
{
```

```
    #body of the function
```

```
    return(result);
```

```
}
```

The red parts are defined by programmer!

---

# How to Use Own Function

---

```
Function_Name = function(arg1, arg2)
```

```
{
```

```
    #body of the function
```

```
    return(result);
```

```
}
```

```
re = Function_Name(var1,var2)
```

Notice: relationships between var1, var2, re and arg1, arg2, result
